*[Continued on next page]*

(54) Title: PREDICTIVE CACHING AND HIGHLIGHTING OF WEB PAGES

(57) Abstract: A web browser predictively and automatically searches for web documents linked to a currently displayed web page which contain terms of interest to a web browser user. Linked documents containing terms of interest are automatically retrieved and stored while the user views the current document such that if the user selects the link to stored document, it will be displayed without waiting for it to download. To further assist the user in finding the documents containing the user's interest terms, links in the current page leading to the documents of interest are highlighted, and special fast links to those pages may be created and displayed for even greater noticeability and usability by the user

## PREDICTIVE CACHING AND HIGHLIGHTING OF WEB PAGES

## BACKGROUND OF THE INVENTION

### Field of the Invention

This invention relates to the technology of web browsers and
servers, and especially to the web browsing technologies which provide
browsing capabilities prioritized and keyed to a user's personal
interests.

### Description of the Related Art

The Internet and the World Wide Web have become critical, integral
parts of commercial operations, personal lives, and the education process.

At the heart of Internet is web browser technology and Internet
server technology.

An Internet server contains "content" such as documents, image or
graphics files, forms, audio clips, etc., all of which is available to
systems and browsers which have Internet connectivity.

Web browser or "client" computers may request documents from web
addresses, to which appropriate web servers respond by transmitting one or
more web documents, image or graphics files, forms, audio clips, etc.  The
most common protocol for transmission of web documents and contents from
servers to browsers is Hyper Text Transmission Protocol ("HTTP").

FIGURE 1 shows the fundamental client-server arrangement of Internet
and intranet communications.  A client browser computer (1) is provided
with Internet access (2) to the World Wide Web (3) through common means
such as a dial-up telephone line and modem, cable modem, or local area
network ("LAN").  The web browser computer (1) is also provided with
appropriate web browsing software, such as Netscape's Navigator or
Microsoft's Explorer.  A web server computer (5) is likewise provided with
Internet access (4) to the World Wide Web (3) using similar means, or
higher-bandwidth means such as T1 and T3 data lines, and a web server
suite of software.  Alternatively, client and servers may be
interconnected via an Intranet (6), such as a corporate LAN.  These
arrangements are well known within the art.

The most common type of Internet content or document is Hyper Text
Markup Language ("HTML") documents, but other formats are equally well
known in the art, such as Adobe Portable Document Format ("PDF").   HTML,
PDF and other web documents provide "hyperlinks" within the document,
which allow a user to select another document or web site to view.
Hyperlinks are specially marked text or areas in the document which when
selected by the user commands the browser software to retrieve or fetch
the indicated document.

Ordinarily, when the user selects a plain hyperlink, the current
page being displayed in the web browser's graphical user interface ("GUI")
window disappears and the newly received page is displayed.   If the parent
page is an index, for example the IBM web site www.patents.ibm.com, and
the user wishes to visit each descending link (e.g. read the document with
tips on how to use the site), then the parent or index page disappears and
the new page is displayed (such as the help page).

As the computing capacity of web browser computers increase and the
communications bandwidth to the web browser computer increase
dramatically, one challenge for organizations who provide Internet web
sites and content is to deliver and filter such content in anticipation of
these greater processing and throughput speeds.

This is particularly true in the realm of web-based applications,
and in the development of better and more efficient ways to move
user-pertinent information to the desktop or client.

However, today's web browsers are in general unintelligent software
packages.  As they currently exist, they require the user to manually
search for any articles or documents of interest to him or her, and are
often cumbersome in that they frequently require download of many
documents before one of germane interest is found.

Search engines provide some level of "intelligence" to the browsing
experience, wherein a user may point his unintelligent web browser to a
search engine address, enter some keywords for a search, and then review
each of the returned documents one at a time by selecting hyperlinks in
the search results, or by re-pointing the web browser manually to provided
web addresses.  However, search engines do not really search the entire
Internet, rather they search their own indices of Internet content which
has been built by the search engine operator, usually through a process of
reviewing manual submissions from other web site operators.  Thus, it is

common for a user to use several search engines while looking for information on a particular subject, because each search engine will return different results based on their own index content.

To partially address this problem, two other technologies have been developed and are well-known in the art. The first technology is known as a "metasearch engine" which is a search engine of search engines. A metasearch engine does not keep its own index, but rather submits a query to multiple search engines simultaneously, and returns to the user the highest ranked returns from each of the search engines. While this is more useful than manually serially visiting each of the queried search engines, the results are typically less satisfying than would be expected. Commonly, the top few returns on a list of ranked matches to the search keywords are not the most interesting, and so more often than not, a user visits the sites listed towards the middle or end of the return list. The metasearch engine may, though, return the top 5 of listings from 4 search engines, which may filter out the more likely interesting information.

The second attempt at solving this problem is known as web "crawler" engines. These servers periodically contact other servers to "re-index" previously indexed web site content, which tends to keep them more up-to-date and incorporates into their index any newly available information a web site. However, since thousands of new web sites are brought on-line each day, it is practically impossible for a crawler to visit new sites. So, even web crawlers may not provide full coverage of internet content.

Other attempts, including creating a "community of intelligent agents", use of server-based interactive sorting and filtering, a client-side "intelligent assistant" triggered by encountering special tags within a web document, and automatic "bookmark" functions, have been proposed in various US patents. In general, all of these proposed technologies and methods require some amount of server-side and client-side cooperation, making it difficult to deploy these technologies on a wide scale.

Several years ago, client-side technology was introduced to download all web pages within one hyperlink of the web page currently loaded by the browser. By gathering all the directly linked documents from the currently visited page, whichever one the user next selected would be immediately available from a cache in local memory, thereby eliminating the wait for the newly selected page to be transmitted from the server to

the web browser.  By the time the user finished reading the next page (now
the current page) and selected a subsequent document, the subsequent
document had already been cached so that it, too, could be displayed
without transmission delay. However, this process has shortcomings when
visiting a "link-rich" web page.  For example, a web page of a popular
news site may have over 60 directly linked documents from the new
service's home page.  Thus, the communications network serving the web
browser computer may pose a bottleneck or time-limiting factor for loading
all 60 directly linked documents while the user reads the home page, and
before the user selects a hyperlink on the home page.  As such, only a few
of these directly linked pages might be successfully downloaded in the
time that it takes the reader to peruse the home page and to make a
decision on the next document to view.  Unfortunately, the pages that were
successfully downloaded during the review of the home page may be of no
interest to the user as the downloading function has no means for sorting
or determining which pages may or may not be of interest.

## SUMMARY OF THE INVENTION

The present invention accordingly provides, in a first aspect, a
method for predictively browsing for web documents of potential interest
to a user of a web browser system, said web browser system having a user
display, a user input device, and a persistent storage device, said web
documents containing words and being accessible through a linked address
from said web browser system, said method comprising the steps of:
receiving a portion of a web document from a linked address; determining
if said portion of a web document contains one or more predetermined words
of interest to said user; and responsive to determining one or more words
of interest are present in said document portion, receiving and storing an
entirety of said web document.

The method of the first aspect preferably further comprises
repeating said steps of receiving a portion of a web document, determining
if said portion contains interest words, and receiving and storing an
entirety of a web document for a plurality of web documents accessible
within a predetermined number of linked addresses from a first web
document.

The method of the first aspect preferably further comprises the step
of providing special user highlighting of a link to a web document on said
web browser display.

The method of the first aspect preferably further comprises creating a fast link to said stored web document on said web browser display.

In a second aspect, the present invention provides a computer program comprising program code to, when loaded into a computer system and executed, cause said computer system to perform all the steps of a method of the first aspect.

In a third aspect, the present invention provides an enhanced web browser system capable of predictively browsing for web documents of potential interest to a user of a web browser system, said web documents containing words and being accessible through a linked address from said web browser system, said system comprising: a processor for executing program code; a user display for presenting information to a user; a user input device for receiving user input; a persistent storage device for storing data and information, including a user interest term list stored therein, said interest term list containing words of interest to the user; and a predictive interest-based browser program executable by said processor, said browser program adapted to receive a portion of a web document from a linked address, determine if said portion of a web document contains one or more interest term words, receive and store an entirety of said web document responsive to determining one or more interest term words are found in said document portion.

Preferably the predictive interest-based browser program of the system of the third aspect further comprises a standard web browser program with a browser plug-in, said browser plug-in being adapted to receive a portion of a web document from a linked address, determine if said portion of a web document contains one or more interest term words, receive and store an entirety of said web document responsive to determining one or more interest term words are found in said document portion.

Preferably said web documents comprise HTML documents.

Preferably the system of the third aspect further comprises a link highlighter for highlighting a link to a stored web document on said web browser display.

Preferably the system of the third aspect further comprises a fast link creator, said fast link on said web browser display pointing to said stored web document.

The present invention thus suitably and preferably allows the web
browser to predictively and automatically search for web documents linked
to a currently displayed web page which contain terms of interest to the
web browser user.  Linked documents containing terms of interest are
suitably automatically retrieved and stored while the user views the
current document such that if the user selects the link to stored
document, it will be displayed without waiting for it to download.  To
further assist the user in finding the documents containing the user's
interest terms, links in the current page leading to the documents of
interest may be highlighted, and special fast links to those pages may be
created and displayed for even greater noticeability and usability by the
user.

Preferred embodiments of the present invention thus advantageously
provide a web browsing method and system which predictively retrieves
information from computer network servers and distributed databases, such
as the World Wide Web, based upon a user's list of interest terms or
keywords.  Further, it is advantageous for this new system and method to
be compatible with widely-used web browser technologies, such as personal
computers, web-enabled telephones, Internet appliances, personal digital
assistants, and pocket PCs, with minimal or no server-side support or
cooperating technology.  Additionally, it is advantageous for this new
system and method to highlight predictively cached information, or links
to such information, on a user's display such that the user may easily and
quickly view the predictively cached information.

Preferred embodiments further preferably provide a system and method
for configuring a web browser system to include a list of interest terms
for a user.  This method provided a list of the user's most sought-after
keywords, the list being available to other software programs on the same
client web browser computer.

## BRIEF DESCRIPTION OF THE DRAWINGS

A preferred embodiment of the present invention will now be
described, by way of example only, with reference to the accompanying
drawings, in which:

FIGURE 1 shows the well-known arrangement between Internet clients
or web browser systems, web server systems, and communications networks.

FIGURE 2 illustrates the well-known architecture of web browser and web server systems.

FIGURE 3 shows a typical tree-like structure of hyperlinked documents on a web site.

FIGURE 4 discloses the arrangement of the preferred embodiment of the invention.

<u>DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT</u>

For the purposes of this disclosure, it is assumed that all tasks associated with seeking out and loading web pages are conducted by a web browser application, such as Netscape's Navigator or Microsoft's Explorer. In practice, embodiments of the invention described herein may be realized in web-browser associated software, which may or may not be part of the browser itself, such as a cooperating stand-alone software application or a web browser plug-in module. As such, it will be recognized by those skilled in the art that the construction of interest term lists, as described herein, can be accomplished by any piece of software, the results of which can be made available to other browser-related functions and software.

FIGURE 2 shows the general hardware and software architectures of typical web servers and web browser computer systems. A web browser computer (20) is communicatively interconnected via an Internet or intranet (21) to a web server computer (22). The web browser system comprises standard user interface devices (23) such as a computer display or monitor, keyboard, and mouse. The web browser computer (20) hardware platform comprises a central processor ("CPU") (24), disk drives (25), user interface device I/O (26), and network interface card ("NIC") (27). The NIC may be one of several varieties well known within the art, including a dial-up modem, local area network ("LAN") card, or cable modem interface. The software executed by the web browser computer (20) may include device drivers and a basic input/output system ("BIOS") (28), and operating system (203), application programs (202), and an applet interpreter (29) and applets (201). A web browser program, such as Netscape's Navigator, is an application program which can be executed by the CPU (24). This architecture and arrangement with a web server computer is well known within the art.

In the preferred embodiment, a standard web browser application
software program is modified to include certain logical and functional
enhancements. The functional enhancements utilize several existing
capabilities of the existing web browser, such as the abilities to:

(1)     interpret received web documents;

(2)     cause all or part of a web document to be displayed in the current
        web browser display window;

(3)     display user option icons, drop down lists or other mode control
        indicators in the web browser display window;

(4)      receive user selections of user option icons, drop down lists and
        other mode control indicators in the web browser display window; and

(5)     create, store and access data items such as files, records, and
        cookies in system memory, especially persistent memory such as hard
        disk drives and non-volatile RAM or ROM.

As the foregoing general arrangement and architecture of a web
browser system is well-known in the art, the remaining description of the
preferred embodiment of the invention is given relative to steps and
functions preferably implemented as a browser plug-in for Netscape's
Navigator running under Microsoft's Windows[TM] operating system on an
IBM-compatible computer. However, it will be recognized by those skilled
in the relevant arts that alternate operating systems, such as UNIX ,
Linux and Sun Microsystem's Solaris, alternate computer hardware such as
IBM's RS6000, Apple's iMac (TM), personal digital assistants  and
web-enabled telephones, as well as alternate software embodiments such as
Java scripts or compiled programs may be adopted without departing from
the scope of the present invention. In still other embodiments, web
server servelets or programs may maintain the interest term list, making
that list available to client-side programs and plug-ins upon request.

Preferred embodiments of the invention improve on this original
concept and functionality of web browsers in general. It is preferred that
the web browser determine what keywords may be of interest to the web
browser user.  These interest terms are preferably stored in system
persistent memory and are accessible as a flat text file by the present
invention.  Alternative embodiments of the interest term list, such as
records in a database, may be used, all of which are readily accessible by

other programs including the browser plug-in of the preferred embodiments
of the invention.

Other methods or systems for creating the interest term list may be
utilized in conjunction with preferred embodiments of the invention,
however the system and method describede above provides several useful
methodologies for generating the interest term list.

Table 1 shows an example of the interest term list embodiment after
it is generated.  This example user's interest term list is provided in a
comma-separated variable ("CSV") format wherein a colon ":" is defined to
indicate a general category for which sub-categories are specified.  If no
colon follows a category or term, it is assumed that all sub-categories
and terms available under that category are of interest.

```
_ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _

        TABLE 1: Example User's Interest Term List File

_ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _

        Politics <CR>
        Sports: Baseball, Professional Basketball, Motor Sports <CR>
        <EOF>

_ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _
```

The user's interest term list is preferably directly user-editable
so that  if a user wishes to delete an interest term which may have been
added earlier, he or·she may do so easily with a common text file editor
or database program.  Similarly, if  a user wishes to add an interest term
at a later time, he or she should have the option of re-invoking the menus
or directly editing a file to do so.

The preferred embodiments of the invention provide two
user-selectable processes for predictively retrieving and caching
information from web servers based upon a user's interest term list.  In
the first process, only "interest-term" specific hyperlinked information
will be preemptively cached, providing an improvement over the well-known
process of caching all "1 hop" web pages by web browsers.  The second
process disclosed herein highlights any hyperlinks which lead to
information containing the user's interest terms in order to bring these
links to the user's attention, such as by highlighting text or images on
the web browser display, panning within a separate web browser window, or
within a special frame in the primary web browser window.

For better clarity and specificity in the following detailed
disclosure, the following terminology is used:

- "interest terms" are those words or phrases, in a self-explanatory
  fashion, in which the end-user has an interest;
- "N hop scan" signifies the link space within which the web browser will
  attempt to predictively load and examine web pages and associated
- text;
- "interest links" are those hyperlinks accessible within an "N hop scan"
  which contain interest terms;
- "fast link" is a highly visible link, removed from the clutter of a
  display of a normal web page which contains a direct link to a
  discovered page containing interest terms;
- "deep-linking" is a commonly accepted term which refers to pulling web
  content from deep within an organization's website, or otherwise
  retrieving data through a series of URLs, without necessarily loading
  or visiting the intermediate web pages;
- "contemplation time" is defined as the time spent by the user on a
  given web page, which is the time available for the web browser system
  to determine and highlight any interest links branching off of the
  currently loaded web page; and
- "TB" is the size of text, such as in bytes, downloaded as the browser
  scans a page for interest terms.

An N-hop scan, as discussed above, is a predictive scan or retrieval
of documents which are reached within "N" hyperlinks from the starting
point.  A typical tree-like structure or representation of a web site
content is shown in FIGURE 3.  Each page has hyperlinked pages from it,
the hyperlinks being shown as the arrow lines from a page to another page
or pages.  The variable "N" describes the depth or space within which
information is found relative to a starting point.

For example, a 1-hop scan (e.g. N=1) (51) retrieves all hyperlinked
documents accessible via a single "click" or hyperlink from the current
web page (50), namely pages 2, 3, and 4 in this example, and the web page
contents of these documents are scanned for occurrences of the user's
interest terms.

Likewise, a 2-hop scan (N=2) (52) will retrieve all documents
hyperlinked and accessible via two "clicks" from the current web page,

such as all the pages of the 1-hop scan plus pages 2a, 3a, 3b, 4a, and 4b
in this example.

From the tree-like expansion of this diagram, it can be seen that
the amount of data to be considered may grow exponentially relative to the
value of N, and higher order scans will be more practical with further
increases in computer network communications bandwidth and web browser
computer processor speed.

Turning to FIGURE 4, the realized structure of the preferred
embodiment is shown.  The interest term predictive scanner plug-in (43)
runs within the environment of the web browser program (40) on a web
browser computer (20), using the web browser computer's user I/O (23)
facilities to display to the user highlighted links, fast links, and
spawned display frames, as discussed in the following description.  A
user's interest term list (42) in a simple text file or database records,
is accessed from it's storage medium (41), such as on a hard drive or in
persistent memory of the web browser system (20).  Alternatively, the
user's interest term list (42) may be accessed from a web or network
server where it is accessible by the web browser system (20).

The interest term predictive scanner plug-in (43) also uses the
communications capabilities of the web-browser computer (20), such as its
network interface card and communications protocol (TCP/IP), and the web
browser program's (40) communications and display capabilities, such as
HTTP, to selectively retrieve portions of web documents from the Internet
(3) or other computer network.

Preferred embodiments of the invention operate during the
contemplation time for a current web page to predictively retrieve
hyperlinked documents within a N-hop scan space based upon the user's
interest terms.   It assumes that interest keywords can be stored within
the web browser system and/or associated software.  Subsequently,
knowledge of such interest terms is exploited by "read-ahead" predictive
downloads.

The predictive caching process commences as soon as a web browser
loads any web page following a user's selection of that page or other
action to select a page, such as selection of a bookmark, navigation
button, etc.  The currently loaded and viewed web page is set  to the
starting point, or "current page", of the N-hop scan.

12

The preferred embodiments of the invention then parse the current page source, such as the HTML of the current page,  and begin downloading of all web pages directly linked to the current page, referred to as the 1-hop pages.  Downloading of each page is interrupted after successful receipt of a predetermined amount of data, such as the number of bytes or kilobytes defined by TB.

Next, the downloaded portion of each page is scanned to determine if they contain any occurrences of any of the user's interest terms.  If, after the predetermined number of bytes are downloaded, any of the user's interest terms are not found within either the plain text or metawords of the web page, the download is aborted.  By aborting the full page download, the browser preserves both network bandwidth and time; these preserved resources are then used instead to scan at the next possible interesting page.  If interest terms are found, the download is resumed and completed and the entire linked page is stored in cache.

While the user continues contemplating the currently loaded page, the browser looks at the next 1-hop page, and the next, until all 1-hop pages are scanned and cached as necessary.

If all 1-hop pages are scanned before the user finishes reviewing the current page, the hop level is incremented, and subsequent levels of depth of the web site content are scanned by downloading portions of each 2-hop, then 3-hop, etc., page, scanning for keywords, and caching the entire page if interest terms are found, as previously described.

The predictive scanning process may be described by the pseudocode of TABLE 2.

```
_ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _

      TABLE 2: Pseudocode for Predictive Scanning Process

_ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _

UNTIL (user selects a link in current_page):
  FOR hop = 1 to N:
        scan_page = current_page
        catalog all referenced_links from current_page
        randomly order from first to last all referenced_links
        FROM first TO last referenced_link:
              download document portion at referenced_link
              scan portion for occurrences of interest terms
              IF occurrences found, THEN:
                    complete download of document
```

```
                store document in cache
                highlight referenced_link
                create "fast link" to cached document (optional)
        ELSE discard portion of document
    NEXT  referenced_link   /* scan next portion of linked
                                    document in this hop */
    NEXT hop /* scan next set of documents one hop further from
                                    current pg */
```

— — — — — — — — — — — — — — — — — — — — — — — — — — — — —

As one-hop pages are discovered to contain the user's interest
terms, they are then brought to the user's attention by any one of several
methods.  First, the hyperlink or links leading to the page containing the
interest terms may be highlighted in the display of the current page, such
as by changing the color, font or size of the display of the hyperlink.
In an enhanced embodiment of the invention, a "fast link" may be created
within a separate frame on the current window, either along one side, the
top, or the bottom, of the current page or within a separate web browser
window.

This provides the user a modified web browser display which
highlights links which are more likely to lead to documents of interest to
the user, according to his or her interest term list, and allows the user
to more efficiently browse the current web site.

It should be noted that if fast link display is used, multi-hop
interest links can be one-hopped, that is, the next step in the path to
the interest link is shown, after which the next step in the path is
shown, etc., or they can be "deep linked."  In this latter case, the first
link shown in the frame, window, etc., deep links to the interest item,
even if it is accessible only through multiple hops, and the display of
that top level first link may be highlighted.  In a further refined
embodiment of the invention, one highlighting method may be used to
highlight one-hop links to interesting documents, while another
highlighting method can be used to highlight multi-hop links to
interesting documents.  For example, one-hop interesting links could be
set to blink in red text, while multi-hop links to interesting documents
may be shown or highlighted in steady red text.   HTML code to set colors,
font, and blink attributes are well known, so the browser plug-in of the
preferred embodiment must simply changes these attributes for the web
browser display of that portion of the current web page.

14

Also note that the preferred embodiments of the invention undertake a "breadth-first search," rather than drilling down through "N hops" from one given starting point. Alternatively, a "depth-first search" could also be undertaken, although it is deemed less practical and efficient from the inventor's viewpoint as links not contained in the initially-downloaded document portions may be missed or skipped. Either search technique may be used with general applicability of the concepts disclosed here.

It should also be recognized that a common list of interest page "fast-links" can be maintained in the separate window or frame, if desired, even if a user progresses down one particular path. Consider, for instance, a user at web page "A" who is given a list of interest links "B" and "C". It may be readily observed that the user would progress to interest link "B" while still maintaining a fast-link to web page "C" in the separate frame or window. After reading "B," and presuming that interest links arrived while doing so, maintenance of "C" in a fast-link window would permit him or her to immediately jump back to the other path, not previously taken.

By incorporating the preferred embodiments of the invention into a web browsing system or product, a more intelligent means of browsing the vast total content of the World Wide Web and its constituent web sites based upon the user's interests is enabled.

While specific examples and details related to a preferred embodiment have been set forth herein, it will be recognized by those skilled in the art that various alternatives and engineering choices may be made without departing from the scope of the present invention, including but not limited to realization of the method as an application program, portable language script, server-side program or script, or browser enhancement; use of a different web browser computer such as a web-enabled telephone, Internet appliance, or personal digital assistant; and use of an alternative operating system such as Windows[TM] CE.

## CLAIMS

1.    A method for predictively browsing for web documents of potential
interest to a user of a web browser system, said web browser system having
a user display, a user input device, and a persistent storage device, said
web documents containing words and being accessible through a linked
address from said web browser system, said method comprising the steps of:

       receiving a portion of a web document from a linked address;

       determining if said portion of a web document contains one or more
predetermined words of interest to said user; and

       responsive to determining one or more words of interest are present
in said document portion, receiving and storing an entirety of said web
document.

2.    A method as claimed in Claim 1 further comprising repeating said
steps of receiving a portion of a web document, determining if said
portion contains interest words, and receiving and storing an entirety of
a web document for a plurality of web documents accessible within a
predetermined number of linked addresses from a first web document.

3.    A method as claimed in Claim 1 further comprising the step of
providing special user highlighting of a link to a web document on said
web browser display.

4.    A method as claimed in Claim 1 further comprising creating a fast
link to said stored web document on said web browser display.

5.    A computer program comprising program code to, when loaded into a
computer system and executed, cause said computer system to perform all
the steps of a method as claimed in any of claims 1 to 4.

6.    An enhanced web browser system capable of predictively browsing for
web documents of potential interest to a user of a web browser system,
said web documents containing words and being accessible through a linked
address from said web browser system, said system comprising:

       a processor for executing program code;

       a user display for presenting information to a user;

a user input device for receiving user input;

a persistent storage device for storing data and information, including a user interest term list stored therein, said interest term list containing words of interest to the user;

and a predictive interest-based browser program executable by said processor, said browser program adapted to receive a portion of a web document from a linked address, determine if said portion of a web document contains one or more interest term words, receive and store an entirety of said web document responsive to determining one or more interest term words are found in said document portion.

7.    A system as claimed in Claim 6 wherein said predictive interest-based browser program comprises a standard web browser program with a browser plug-in, said browser plug-in being adapted to receive a portion of a web document from a linked address, determine if said portion of a web document contains one or more interest term words, receive and store an entirety of said web document responsive to determining one or more interest term words are found in said document portion.

8.    A system as claimed in Claim 6 or Claim 7 wherein said web documents comprise HTML documents.

9.    A system as claimed in any of Claims 6 to 8 further comprising a link highlighter for highlighting a link to a stored web document on said web browser display.

10.    A system as claimed in any of Claims 6 to 9 further comprising a fast link creator, said fast link on said web browser display pointing to said stored web document.
